16 **Abstract**

17 This study aims to characterize the estrous cycle of *Asinina de Miranda* jennies in the
18 breeding season, based on data collected from serial ultrasonographic examination
19 and serum progesterone (P4) determinations in 14 females during a total of 33
20 cycles. The length of the interovulatory interval was 23.8 ± 0.55 days, the diestrus
21 and estrus lasting 17.9 ± 0.46 days and 6.65 ± 0.30 days, respectively. Age and body
22 condition score (BCS) affected the length of the interovulatory intervals; BCS also
23 influenced the diestrus length and the time in heat after ovulation ($p > 0.05$). The
24 incidence of single, double and triple ovulations was 57.58%, 36.36% and 6.06%,
25 respectively. Multiple ovulations affected neither the length of the interovulatory
26 interval, nor the individual cycle stages ($p > 0.05$), but lengthened the interval from
27 beginning of estrus to last ovulation ($p = 0.01$). When combined with age, higher BCS
28 affected the ovulation rate ($p = 0.001$). Deviation of the dominant follicle occurred
29 around day -8.7 (day 0 = ovulation) when both single and multiple ovulations were
30 considered. The dominant follicle was larger at divergence in single ovulators (19.18
31 ± 0.97 mm) compared to multiple ovulators (18.05 ± 1.16 mm). The overall maximum
32 follicular diameter before ovulation was smaller in multiple ovulatory cycles than in
33 single ovulatory cycles (37.2 ± 0.83 mm vs. 40.2 ± 1.41 mm, respectively; $p = 0.03$).
34 The daily growth rate of dominant follicles was independent of the ovulation rate ($p >$
35 0.05) for the intervals prior and after estrus onset. The dominant follicle size and the
36 follicle growth rates were independent of BCS ($p > 0.05$). Data collected in this study
37 revealed resemblances between Mirandese and other Iberian and Brazilian breeds
38 with regard to estrous cycle characteristics.

39

40 **Keywords:** donkey, reproduction, body condition score, ovulation, follicle.

41 1. Introduction

42 The *Asinina de Miranda* is an endangered breed of donkey originating from the far
43 north east of Portugal. It is characterized by having a long bay coat, a height of over
44 130 cm and a calm temperament, which makes it especially suited to agricultural
45 work, milk production and leisure activities such as asinotherapy. With around 500
46 females available for reproduction, the breed exhibits very low rates of reproduction.
47 Less than a quarter of existing *Asinina de Miranda* jennies have had foals registered
48 in the studbook [1]; the average foaling rate over the past 10 years has been close to
49 50 foals a year, though this number has increased to around 70 foals a year in the
50 last 2 years [2]. Average age at first foaling has increased in recent decades and for
51 a large proportion of females introduction into reproduction has been postponed until
52 a later age, when fertility tends to decline and reproductive disorders become more
53 prevalent [3]. The fact that most traditional owners show little interest in breeding
54 seems to be the reason for this late entry into reproduction, together with the lack of
55 any need to replace working animals [1, 2]. More recently, under the guidance of the
56 national Breeding Association (AEPGA) and following new trends such as breeding
57 females for milk production, a growing number of young jennies are now being put
58 into breeding [1,2].

59 The *Asinina de Miranda* is an endangered breed, despite attempts to raise interest in
60 it by identifying alternative uses for these animals. It has been suggested that the
61 number of females breeding each year be increased and that jennies should enter
62 into reproduction earlier than is currently usual in an effort to increase foaling [1,2].
63 As there is such a limited amount of available information, this confirms the need for
64 greater research into the reproductive physiology of the species. Milk production is
65 one potential use of donkeys that has recently been exploited and could provide the
66 means of preventing extinction for many breeds, including the *Asinina de Miranda*;

67 however, productive optimization requires greater knowledge of the donkey's
68 reproductive physiology in order to increase foaling rates [4]. Detailed knowledge of
69 the characteristics of the estrous cycle in *Asinina de Miranda* jennies is vital in order
70 to improve the reproductive management of the breed and increase reproductive
71 efficiency. Furthermore, knowledge into how follicles develop as well as their size at
72 specific moments in this process (such as at deviation or at ovulation) is
73 fundamental to pharmacological manipulation of the cycle or to exogenous induction
74 of ovulation.

75 Jennies are similar to mares in many reproductive aspects but tend to have longer
76 breeding seasons [5, 6], as well as longer diestrus phases [7]. Consequently,
77 donkeys have longer interestrus intervals [5, 8, 9], similar to those reported for
78 ponies [7]. The estrus length is similar among jennies, ponies and mares [7, 10, 11],
79 ovulation usually occurring 1 to 2 days before the end of estrous behavior [6, 9, 10],
80 as is also found in mares [12].

81 There are a few studies available on the characteristics of the estrous cycle for other
82 European donkey breeds [7, 11, 13, 14]. However, there have only been a limited
83 number of comparative studies into differences in donkey breeds, like those known to
84 exist in breeds of horse [15], surveying characteristics such as the rate of ovulation
85 and the prevalence of multiple ovulations, the size of the ovulatory follicle, and the
86 moment of ovulation within the follicular stage. Such characteristics are yet to be
87 determined in *Asinina de Miranda*. In order to implement conservation programs
88 aimed at rescuing the breed, it is crucial that assisted reproduction is considered,
89 with particular regard to follicular development and the putative factors that may
90 affect it [16, 17].

91

92 This study aims to characterize the estrous cycle of *Asinina de Miranda* jennies
93 during the breeding season, including: the lengths of the interovulatory interval and of
94 the estrus and diestrus stages; the ovulation rate (number of ovulation per estrus)
95 and the prevalence of multiple ovulations; the maximum follicular size prior to
96 ovulation, considering both single and multiple ovulations; the pattern of final follicular
97 growth, from the beginning of estrus detection up to ovulation; the laterality of
98 ovulation; and the length of time in heat after ovulation. Furthermore, the putative
99 influences of endogenous factors such as age and BCS were also tested.

100

101 **2. Material and methods**

102 *2.1. Animals, management and sample collection*

103 This study used 14 non-pregnant clinically healthy jennies of the Portuguese *Asinina*
104 *de Miranda* breed of donkey. The jennies were aged from 3 to 18 years: 6 young
105 jennies aged between 3 and 5 years, 6 adult females aged between 6 to 8 years and
106 2 older females aged over 15 years. This distribution attempts to reflect the age
107 pyramid seen in breeding females [2]; the small number of females in the older group
108 was due to exclusion because of ovarian diseases. All the jennies had body condition
109 scores ranging from 4 to 7 on a 9 point scale (5.7 points on average). BCS was
110 regularly evaluated during the breeding season, at 5-week intervals [18].

111 Data was collected during two breeding seasons, from April to late September, using
112 a group of seven different animals each year. The regular estrous cycles for both
113 groups were studied from April to June, producing a total of 33 estrous cycles. Most
114 jennies were found to have two successive estrous cycles; only 5 females, two from
115 the first year's group and three from the second, recorded 3 cycles. Complete

116 previous reproductive histories were generally unknown in respect to previous
117 pregnancies, but none of the females had foaled in the preceding breeding season.
118 The existence of regular estrous cycles was confirmed before the onset of the study.
119 All the jennies were considered potentially fertile after a breeding soundness exam.

120 The animals were housed in Vila Real, Portugal (41°17'N 7°44'W), in the University
121 facilities, and kept under natural photoperiod. All the animals were routinely
122 vaccinated for equine influenza and tetanus (Proteq-Flu TE™, Merial S.A.S., Lyon,
123 France) and dewormed every 6 months with 200µg Ivermectin (Noromectin Oral
124 Paste, Norbrook Laboratories, Northamptonshire, UK) per kg of bodyweight. The
125 jennies were kept in a 2,500 m² paddock, with a 50 m² shelter offering year-round
126 protection from rain, sun and wind. The animals were fed according to accepted
127 protocols [19], consisting of 5–7 kg of hay and straw per jenny twice daily, which
128 corresponded to a dry matter intake of between 1.5% and 2% of body weight,
129 supplemented with 1kg of concentrate, divided into two daily portions. Clean fresh
130 water was always available. The animals were handled in accordance with EU
131 Directive 2010/63/EU for animal experiments.

132 The females were group teased daily by a male with a good libido, and their estrous
133 behaviour classified as follows [7, 20]: The female was considered to be in estrus or
134 receptive if she exhibited mouth clapping together with at least one of the following
135 signs during the teasing period: winking (rhythmic eversion of the vulvar *labiae* with
136 exposure of the clitoris) and urinating; raising the tail; and posturing. In contrast, non-
137 receptivity behaviour included: 1) tail down (holding tail down between hind legs
138 when mounted); 2) lack of interest (no positive or negative responses to the presence
139 or teasing of the jack); and 3) refusing the jack by moving away or kicking. Clapping

140 alone, or combined with kicking or moving was considered to indicate a transitional
141 stage into or out of estrus, but not recorded as receptive behaviour.

142 For teasing, the male was placed in a paddock adjacent to the jennies, separated by
143 a wire fence. The behaviour of the females was observed and recorded for 30
144 minutes; thereafter, the jack was removed to a box within a closed building, 400
145 metres away from the females.

146 For progesterone measurements, blood samples were collected by venipuncture of
147 the jugular into serum-gel tubes (S-Monovette®, Sarstedt, Nümbrecht, Germany),
148 preceding the ultrasound session, and placed in ice. Samples were centrifuged after
149 collection at 2500 X g for 10 min; serum was harvested and stored at -20°C until
150 assayed. Serum progesterone concentrations were determined by chemiluminescent
151 immunoassay (IMMULITE 1000®; Siemen's Medical Solutions Diagnostics, Los
152 Angeles, CA, USA), using a commercial progesterone kit (Siemens Immulite®
153 Progesterone Kit) and commercially available reagents (all from Siemens Healthcare
154 Diagnostics, Amadora, Portugal). Interassay coefficient of variance for the controls
155 (respectively CON4, CON5 and CON6 for low, intermediate and high controls -
156 Multivalent Control Module, Siemens) ranged from 1.3 and 1.5% for the lower and
157 intermediate controls, to 4.6% for the high control. To validate the progesterone kit
158 for donkeys, serial dilutions in buffer of a blood sample obtained from a 40-day
159 pregnant jenny were made. The coefficients of regression obtained were 96%.

160

161 *2.2. Ultrasound assessment of reproductive activity*

162 During the trials, the jennies' estrous activity was routinely surveyed every other day
163 in diestrus and at eight to twelve-hour intervals in estrus by transrectal palpation

164 followed by ultrasound (US) examination of the genital tracts using a linear-array US
165 scanner equipped with a 5 MHz linear transducer (Shenzhen Veterinary US
166 scanner), according to the procedures described by Ginther [15]. The scanner was
167 connected to a video camera (DCRHC96E, Sony) and all US scans were recorded
168 for subsequent analysis.

169 The diameters of the ovarian dominant follicles were obtained retrospectively from
170 the average of the narrowest and widest dimensions in selected US scan images,
171 considering only the follicular antrum. One single operator established follicular size
172 measurements, using *ImageJ* software (<http://imagej.nih.gov/ij/index.html>) on fixed
173 frame images. A dominant follicle was defined as the one deviating from other
174 growing follicles, and becoming the largest in the ovary, whether or not it ovulated
175 [21]. The dominant follicle, or follicles in the case of multiple ovulations, was
176 considered ovulatory if it reached ovulation. Day 0 of the cycle was set as the day of
177 ovulation or, in the case of multiple ovulation, as the day of last ovulation.

178 The interovulatory interval was defined as the interval (in days) between estrus-
179 associated ovulation in successive cycles, or as the period between the last ovulation
180 of each cycle in the case of multiple ovulations. Sequential US records were used to
181 establish the moment of ovulation as the mid-time between two US scans when a
182 dominant follicle ceased to be observed during estrus. The beginning of estrus was
183 set at the moment when the female first showed signs of receptivity to the male, with
184 progesterone (P4) levels below 1 ng/ml, while the end of estrus was considered to be
185 the moment when the jenny refused the jack. Diestrus corresponded to the period
186 when serum progesterone levels remained above 1 ng/ml and the female refused the
187 jack [22]. The ovulation rate was defined as the number of ovulated follicles, based

188 on US observation of the collapse of the preovulatory follicle(s) and loss of > 90% of
189 fluid by the time of the next examination [23].

190 2.3. Statistical analysis

191 Statistical analyses were performed using the IBM SPSS Statistics 20 software for
192 Windows®. The estrous cycles were normalized to the day of ovulation (day 0); in the
193 case of multiple ovulations, day 0 was set at the day of last ovulation. For graphical
194 representations, the normalized period was defined as the 12 days following
195 ovulation (day 0). Data for the lengths of the interovulatory interval, diestrus and
196 estrus, the size of dominant follicles, the time in estrus after ovulation and the final
197 follicular growth rate are presented as mean \pm standard error (SE).

198 An ANOVA test was conducted, followed by a Bonferroni post-hoc test for means
199 comparison, in order to analyse the effect of BCS and age on the length of each
200 cycle stage, the ovulation rate, the growth rate and follicle size, the total level of
201 progesterone and the time in heat after ovulation. Total secretion of progesterone
202 during diestrus was assessed by estimating the area under curve, applying the
203 trapezoidal rule, i.e. calculating the $\Delta X \cdot (Y_1 + Y_2) / 2$, using Microsoft® Excell 2010 for
204 Windows. Furthermore, a covariance analysis was used to explore the effect of BCS
205 (main effect) and age (covariable) on the ovulation rate. Possible correlations
206 between the ovulation rate and the length of the cycle phases, the follicular growth
207 rate and follicle size, the total progesterone level and time in heat after ovulation
208 were analyzed by Pearson's chi-square test. Differences and correlations were
209 regarded as significant at $P < 0.05$.

210 Proportional differences were calculated to determine whether the differences in the
211 proportions of multiple ovulations in individual animals were significant.

212

213 **3. Results**214 *3.1. Estrous behaviour*

215 During this study, all jennies in estrus showed homotypical signs of estrous
216 behaviour (i.e. characteristic for the species) such as mouth clapping, clitoral winking,
217 posturing or showing increased interest towards the male. Often, the jennies also
218 exhibited heterotypical behaviour (i.e. signs of estrous behaviour shared among
219 different species), such as the Flehmen response, sniffing, chasing other females or
220 standing to be mounted. Mouth clapping was the first suggestive sign of the
221 approach of estrus, and it was also the last sign to disappear after ovulation.

222

223 *3.2. Length of the estrous cycle stages*

224 The present study surveyed a total of 33 estrous cycles. Cases of anovulatory estrus
225 or of split estrus were not observed. The length of the interovulatory interval was 23.8
226 ± 0.55 days, ranging from 17.6 to 34.7 days. The lengths of diestrus and estrus were
227 17.9 ± 0.46 days (11.6 to 27 days) and 6.65 ± 0.30 days (3.15 to 9.71 days),
228 respectively (Table 1). No significant effect of age on the lengths of estrus ($p=0.682$)
229 or diestrus ($p=0.101$) was found, although longer interovulatory intervals ($p=0.032$)
230 were reported in older jennies when compared with younger females. Higher BCS led
231 to longer interovulatory intervals ($p=0.022$) and diestrus ($p=0.003$), but did not affect
232 the length of estrus ($p=0.944$). During the period surveyed, no individual variations in
233 the length of interovulatory intervals were observed, nor in the length of any phases
234 of the cycle. The ovulation rate did not correlate with the length of the interovulatory

235 interval ($p=0.990$) or diestrus ($p=0.169$). However, the estrus was longer in multiple
236 ovulators than in single ovulators (5.22 ± 0.40 vs. 6.96 ± 0.33 ; $p=0.03$). In addition,
237 the ovulation rate correlated positively with the period from the beginning of estrus to
238 last ovulation ($p=0.01$).

239 In general, ovulation occurred less than 15 hours before the end of the estrus, but
240 jennies maintained estrous behaviour for a variable period after ovulation (Table 1).

241 In 21 of the 33 cycles studied, estrus lasted between 4 to 53 hours after ovulation, for
242 an average period of 26.3 ± 3.27 hours. In the other 12 cycles, the interval between
243 ovulation and the end of estrous behaviour was either shorter than 12 hours ($n=10$)
244 or it occurred before the last ovulation was detected, as in the case of a double
245 ovulation that displayed an interval of 45.5 hours between ovulations, or in a triple
246 ovulation recording an interval of 114 hours between the first and last ovulation. No
247 significant differences ($p=0.508$) were found for time in heat after last ovulation
248 between single (23.7 ± 5.06 hours) and multiple ovulations (26.25 ± 3.27 hours).

249 Although animals displaying higher BCS tended to cease estrous behaviour sooner
250 after ovulation, BCS did not significantly affect the number of hours in heat after
251 ovulation ($p=0.05$). Nevertheless, longer estruses were linked to a lower number of
252 hours in estrus post-ovulation ($p=0.028$).

253

254 3.3. Prevalence of multiple ovulations

255 Of the 33 cycles analyzed, 57.58% ($n=19$) were single ovulators and 42.42% ($n=14$)
256 multiple ovulators, of which 12 (36.36%) were double ovulations and 2 (6.06%) triple
257 ovulations. The number of cycles with multiple ovulations was significantly higher
258 ($p=0.02$) in four jennies, together producing 64.3% (nine in fourteen) of the multiple
259 ovulations recorded in this study. These animals were evenly distributed between

260 young and mature groups, and their BCS ranged from 4 to 5.5 points at the moment
261 of multiple ovulations. For these females the prevalence of multiple ovulatory cycles
262 was significantly higher than in the other multiple-ovulating jennies (81.8% vs 40%,
263 respectively). No influences were found for age or BCS in the prevalence of multiple
264 ovulations in these four animals.

265 In single ovulators, a non-significantly higher frequency of ovulations occurred from
266 the right ovary (57.9%; n=11) compared to the left ovary (42.1%; n=8). In double
267 ovulators (n=12), ovulation occurred from a single ovary on 4 and 3 occasions
268 respectively for the left and right ovaries, while it occurred from both ovaries on 5
269 occasions. In triple ovulators (n=2), two of the follicles ovulated from the right ovary
270 and the remainder from the left.

271 Of the 14 multiple ovulations (12 double and 2 triple ovulations), 7 were considered
272 synchronous, with an interval of less than 24 hours between each ovulation. For the
273 remainder, the mean interval between ovulations was 47.7 ± 7.8 hours (41.8 ± 7.85
274 for double ovulations and 59.4 ± 17.9 for triple ovulations). An unbalanced
275 distribution of ovulations was observed over the length of a day: a higher number of
276 ovulations occurred during daytime (63.3%; n=31) compared to 36.7% (n=18) of
277 ovulations occurring during the night; the distribution was similar between single and
278 multiple ovulations (p=0.612). Higher BCS affected the occurrence of triple ovulations
279 (p<0.001), but generally it did not affect the occurrence of multiple ovulations
280 (p=0.410). When combined with age, higher BCS correlated with a higher ovulation
281 rate (p=0.001).

282

283 *3.4. Growth pattern of dominant follicles*

284 Deviation of the dominant follicle occurred close to day 9 before ovulation. In single
285 ovulators, deviation occurred 8.72 ± 0.40 days prior to ovulation, for a follicle
286 diameter of 19.18 ± 0.97 mm, while in multiple ovulators it occurred on day $8.92 \pm$
287 0.23 before ovulation, regardless of the order of follicle ovulation, for a follicle
288 diameter of 18.05 ± 1.16 mm. The average size of the dominant follicle at the onset of
289 estrus (Table 2) was 25 ± 0.95 mm, differing ($p < 0.001$) in the case of single and
290 multiple ovulations (29.20 ± 1.41 mm and 22.40 ± 1.02 mm, respectively); no
291 differences were recorded in the average size of the dominant follicle at the onset of
292 estrus between triple (23.30 ± 4.24 mm), double (22.20 ± 0.81 mm) ($p = 0.130$) or
293 single (29.20 ± 1.41 mm) ovulations ($p = 0.456$).

294 The overall maximum follicular diameter prior to ovulation was 38.4 ± 0.68 mm (Table
295 2). It was smaller in multiple ovulatory cycles (37.20 ± 0.82 mm) than in single
296 ovulatory cycles ($p = 0.03$): in single ovulations ($n = 19$) the mean maximum follicular
297 diameter was 40.20 ± 1.41 mm, contrasting with 36.70 ± 0.86 mm in double
298 ovulations ($n = 24$) and with 38.60 ± 2.39 mm ($n = 6$) in triple ovulations (Table 2). In the
299 case of multiple ovulations, the maximum follicular diameter did not vary with the
300 order of ovulation, whether double ($p = 0.096$) or triple ovulations ($p = 0.942$) were
301 considered, though the second follicle to ovulate was usually smaller. In double
302 ovulations maximum follicular diameter was 38.30 ± 1.25 and 35.41 ± 1.08 mm for
303 the first and second ovulatory follicle, respectively, while in triple ovulations it was
304 38.20 ± 7.8 , 37.50 ± 1.38 and 40.00 ± 4.39 mm, respectively, for the 1st, 2nd and 3rd
305 ovulated follicle.

306 The ovulation rate did not correlate with the daily growth rate of the dominant follicle
307 neither during the period from deviation to the onset of estrus ($p = 0.854$) nor from the
308 beginning of estrus until ovulation ($p = 0.955$). The daily follicular growth rate during
309 the estrus was significantly higher than in the period from deviation to onset of estrus

310 in single ($p < 0.001$), double ($p < 0.001$) and triple ovulations ($p = 0.004$). Higher follicular
311 size at the onset of estrus and higher daily growth rates of the dominant follicle
312 during estrus were associated with ovulation of larger follicles ($p = 0.001$ and $p = 0.027$,
313 respectively).

314 Dominant follicles reached 30 mm in diameter 4.1 ± 1.13 days before ovulation, in the
315 case of single ovulations, or 2.9 ± 2.47 days before ovulation in the case of multiple
316 ovulations. The follicular growth rate showed a slowdown of
317 -0.124 ± 0.13 mm/hour, as estimated by the difference in diameter between the last
318 two measurements prior to ovulation; this slowdown did not differ significantly
319 between single or multiple ovulations ($p = 0.146$; $n = 23$). BCS did not affect the size of
320 the dominant follicle at the onset of estrus ($p = 0.688$) for this group of *Asinina de*
321 *Miranda* jennies. Nor did it affect the maximum follicular diameter prior to ovulation
322 ($p = 0.818$) or the daily follicle growth rates, during the moments both before
323 ($p = 0.729$) and after the onset of estrus ($p = 0.564$).

324

325 3.5. Serum progesterone

326 Mean serum progesterone levels at 24 hours after ovulation were 0.48 ± 0.14 ng/ml,
327 rising sharply to values of 5.56 ± 0.86 ng/ml by post-ovulatory day 3. Thereafter, and
328 until day 15, progesterone levels rose and remained above 10 ng/ml. Progesterone
329 levels start to drop 2 to 3 days prior to the onset of estrus, around day 15 and 16 of
330 the cycle. In estrus, progesterone levels remained below 0.2 ng/ml until ovulation
331 (Figure 1).

332 The area under the progesterone curve, corresponding to the total level of
333 progesterone in diestrus, was higher in multiple ovulatory cycles than in single

334 ovulatory cycles (283.5 ± 18.6 vs. 272.9 ± 21.5 ; 95% confidence interval; Figure 1)
335 ($P=0.001$).

336

337 **4. Discussion**

338 Donkeys are often described as displaying longer estrous cycles than horses, but
339 similar in length to pony mares [7, 13]. This also applies to *Asinina de Miranda*
340 jennies. The present study found that in spring the interovulatory interval for this
341 breed was close to 24 days, which is in accordance with similar studies on other
342 breeds. Considerable variation for estimates of the estrous cycle in donkeys can be
343 found in the available literature, which in part might be due to the period surveyed,
344 the age of the jennies or the methods used to define the cycle stages.

345 An overall estrous cycle length of 24 to 25 days is currently accepted for the *Catalan*
346 (24.9 days; [13]), the *Anatolian* (25 days; [24]), the Brazilian *Pêga* (24.2 days; [9])
347 and *Marchador* (23 days; [25]), the *Mammoth* (23.3 days; [6]), the *Martina Franca*
348 (23.6 days; [22]) and the *Baudet de Poitou* (25.8 days; [26]). The present study
349 surveyed estrous cycles mainly during spring (from April to June), but in accordance
350 with studies from other teams, little variation in the length of estrous cycle with
351 season is to be expected in donkeys from spring to autumn [6,9, 22].

352 In this study, the estimated mean estrus length for *Asinina de Miranda* (6.56 ± 0.55
353 days) was based on basal progesterone concentrations combined with the exhibition
354 of typical estrous behaviour. This estimate was similar to that reported for other
355 European breeds: 6.7 days for the *Martina Franca* [22]; 6.1 ± 2.1 days for the
356 *Zamorano-Leones* [14]; and 5.64 ± 0.2 days for the *Catalan* [13]. But it was shorter
357 than that reported for the *Baudet de Poitou* (7.5 ± 1.2 days) [26] or for Brazilian
358 donkeys (7.9 ± 2.5 days) [10].

359 In jennies, characteristic signs of estrous behaviour in the presence of the jack
360 include mouth clapping, posturing, tail raising, urinating, and clitoral winking [20]. The
361 main homotypical signs of estrus detected in our study were similar to those
362 described for jennies in other studies and used to delimit the estrus stage [6, 7, 13].
363 The present study was able to obtain a more accurate estimate of the duration of
364 estrus by integrating the behavioural signs of group teased females with individual
365 progesterone measurements, thus overcoming the reported weaknesses of group
366 teasing in donkeys [6].

367 The mean diestrus length for the *Asinina de Miranda* was similar to those reported for
368 *Mammoth* jennies [6] and for the *Martina Franca* [22], but it was slightly shorter than
369 those reported for other breeds: 17.9 ± 0.46 days vs. 19.83 ± 0.36 in the *Catalan* [13],
370 or 19.3 ± 0.6 for standard jennies [7].

371 In the present study, age did not affect the lengths of estrus and diestrus in *Asinina*
372 *de Miranda* jennies. Nevertheless, older jennies displayed longer interovulatory
373 intervals, in accordance with those reported for mares [12]. This might be associated
374 with slower growth of the dominant follicle, as argued by Ginther et al. [27]. This
375 finding could not be ascertained in the present study, due to a disproportionate
376 distribution of ages, with a predominance of younger jennies. Nonetheless, in the
377 group of females surveyed, the interovulatory interval and the duration of diestrus
378 were significantly affected by BCS: higher body condition scores lengthened the
379 interovulatory intervals and diestrus in *Asinina de Miranda* jennies. Although changes
380 in BCS or in metabolites and metabolic hormones such as leptin, insulin or IGF-I
381 have been associated with follicular activity and mare fertility [28, 29], there is a lack
382 of incontrovertible information available on the effect of BCS on conditioned
383 measurements of the duration of each stage of the estrous cycle in cyclic mares [30,
384 31].

385 Moreover, Fitzgerald and McManus [31] reported similar effects of BCS on the
386 characteristics of the estrous cycle, affirming that the length of diestrus and
387 interovulatory interval was greater in fat mares ($BCS \geq 7$) under controlled
388 management than in mares with moderate BCS. The effect of high BCS on the
389 duration of the estrous stages in different studies may incorporate the effect of other
390 parameters, such as the age and breed of the female, the management (controlled
391 vs. free-ranging), the physiological status (post-partum, cyclic) or the extent of the
392 period considered (the entire year vs. the breeding season) or the number of
393 consecutive cycles, limiting the scope of this discussion. It is possible that this also
394 occurred in the present study, as older mares tend to display higher BCS levels than
395 younger mares.

396 Multiple ovulations seem to be higher in donkeys than in horses [15]; the ovulation
397 rate reported in the available literature varies from around 5% to almost 70% [6, 7,
398 10, 13]. It has been proposed that one main factor for this variation in donkeys might
399 be the breed [13], even though no statistical differences were found among three
400 different Spanish breeds [14]. In the present study, the prevalence of multiple
401 ovulations in *Asinina de Miranda* jennies was 42.42%, of which 36.36% were double
402 ovulations and 6.06% triple. These figures were similar to those reported for the 3
403 Spanish breeds – the *Catalan* [13, 14], the *Andalusian* and the *Zamorano-Leonés*
404 [14], but lower than for *Mammoth* donkeys [6].

405 As previously reported in mares [15] and in *Catalan* jennies [13], multiple ovulations
406 were highly repetitive in *Asinina de Miranda* females. According to Ginther [15] this
407 suggests that it may be a heritable trait. The existence of multiple ovulations did not
408 affect the interovulatory interval in *Asinina de Miranda* jennies, although it extended
409 the estrus as well as the interval from the beginning of the estrus until ovulation. Our
410 results are supported by comparable descriptions in Spanish donkey breeds [14]. In

411 the present study, prevalence of multiple ovulations was positively affected by BCS,
412 as has also been reported in mares [32]. Information gathered on multiple ovulations
413 in *Asinina de Miranda* jennies, along with the positive effect of BCS on their
414 occurrence, highlights the need to routinely implement an early pregnancy diagnosis
415 service to identify twin pregnancies and to minimize their risk to the reproductive
416 efficiency of this breed.

417 The frequency of ovulation from each ovary registered in this study was similar for
418 the left and the right ovary, in contrast with that previously reported in horses [15] or
419 donkeys [10]. Yet, Taberner et al. [13] also failed to find evidence of statistical
420 differences in the frequency of ovulation from the left or right ovary in *Catalan*
421 jennies. Multiple ovulations may be classified as synchronous, when ovulations occur
422 at intervals less than 24 hours, or asynchronous, if this interval lasts for more than 24
423 hours. In *Asinina de Miranda* jennies, a similar proportion of synchronous and
424 asynchronous was observed. This contrasts with descriptions of the *Catalan* breed,
425 most of whose ovulations were asynchronous, with intervals ranging from 1 to 9 days
426 [13]. In our study the maximum interval found between multiple ovulations was 2.48
427 days, which is longer than that reported for *Pêga* jennies [9], but resembling that
428 reported for Przewalski's mares [32] or for standard jennies [5].

429 When planning assisted reproductive technologies, knowledge regarding
430 development of the dominant follicle, including its size at the onset of estrus, around
431 ovulation and its daily growth rate, are fundamental for manipulating the estrous
432 cycle and inducing ovulation. In *Asinina de Miranda* these measurements were
433 similar to those reported in other breeds with which the Portuguese breed shares
434 some resemblances in the estrous cycle.

435 In the present study, the dominant follicle was first detected in the ovary as the
436 fastest growing follicle at about 13 days prior to ovulation. The mean follicular

437 diameter at the onset of estrus, corresponding to days 5 to 6 before ovulation in
438 *Asinina de Miranda* jennies, was close to 25mm, which is in accordance with that of
439 the *Brazilian Marchador* [25], but lower than that reported for the *Martina Franca*
440 (around 31.5mm; [22]) in the same season.

441 The dominant follicle reached 30mm around 2.5 to 4 days prior to ovulation, for
442 multiple and single ovulations, respectively. The average maximum follicular
443 diameter observed in jennies in the present study was 38.4 mm, which is similar to
444 that reported for the *Pêga* [9] and *Marchador* [25], or in standard jennies [7]. But it
445 was lower than that recorded in *Catalan* (close to 45mm; [13]) or in *Martina Franca*
446 jennies (43.7mm; [22]). In contrast to the research carried out by Taberner et al. [13],
447 which fails to provide evidence of a link with ovulation type (simple vs. multiple), the
448 maximum follicular diameter was largest in the cases of single rather than multiple
449 ovulations. Similar observations have also been reported in mares [21] and in
450 *Brazilian Marchador* jennies [25].

451 As expected, the daily follicular growth is higher during estrus than in the period
452 between deviation and onset of estrus, as acknowledged in mares [12]. Little
453 information is available for donkeys, as most studies have focused on the follicular
454 growth rate in the 5 days preceding ovulation, which corresponds to estrus. In the
455 present study, the daily growth rate of the dominant follicle was significantly higher
456 after the onset of estrus (3.18 ± 0.18 mm/day) than in the period prior to estrus (2.60
457 ± 0.19 mm/day), independently of the ovulation rate considered. Compared to other
458 studies, the mean daily follicular growth during estrus for *Asinina de Miranda* jennies
459 was slightly higher than that described for the *Brazilian Marchador*, (2.39 ± 0.37
460 mm/day; [25]) or the mare (2.7 mm/day; [15]) but lower than that reported in *Catalan*
461 jennies (3.7 mm/day; [13]). As previously reported for Catalanian donkeys [13], there
462 is a slowdown in the daily growth rate of the dominant follicle on the day preceding

463 ovulation in *Asinina de Miranda*. Such knowledge of follicular dynamics is of utmost
464 importance for controlling ovulation in any breed, enabling drug administration
465 schedules and timing of insemination to be personalized.

466 In the present study, the jennies' BCS did not affect the size of the dominant follicle
467 nor its growth pattern. This seems to contrast with the work of Gastal et al. [16],
468 which showed that in mares the body condition was positively linked with the
469 maximum diameter of pre-ovulatory follicles for the first ovulations of the breeding
470 season. Moreover, Lemma et al. [17] found that BCS was positively correlated to the
471 diameter of the pre-ovulatory dominant follicle in Ethiopian jennies. The relatively
472 constant moderate body condition evidenced by the females in the present study,
473 however, might explain the differences between our results and those referred to
474 above.

475 In general, the cyclic changes in progesterone levels in *Asinina de Miranda* resemble
476 those reported in other donkey breeds [9, 22, 34], as well as in mares [21]. Individual
477 variations are expected both in the onset of progesterone peak and in progesterone
478 levels, as has also been described in mares with estrous cycles of similar length [35,
479 36]; such variations were associated with differences in the secretory capacity of the
480 *corpus luteum* and the hormonal catabolic rate and appear to be more significant in
481 the first 5 days of the diestrus [36]. Moreover, the existence of multiple ovulations
482 and their frequency of occurrence may also influence the levels of progesterone
483 measured. Comparison of progesterone levels in diestrus, using the area under the
484 curve, shows that, in our study, they were affected by the number of ovulations, in
485 accordance with data presented by Meira et al [9] in *Pêga* jennies.

486

487 **5. Conclusions**

488 The present study has enabled identification of the estrous cycle characteristics of
489 *Asinina de Miranda* jennies during the breeding season. Data collected revealed
490 some resemblances with other Mediterranean and Brazilian donkey breeds. It was
491 observed that BCS was positively linked to multiple ovulations and the length of
492 interovulatory intervals; although the jennies maintained a moderate body condition
493 score. Furthermore, jennies with higher BCS appeared to cease estrous behaviour
494 after ovulation faster than those with a lower score. BCS did not affect estrous and
495 diestrous duration *per se*, and neither did it seem to be linked to dominant follicle size
496 and growth rate. The present study also showed that at the onset of estrus, the
497 dominant follicle was about 25 mm in diameter. This study also provides important
498 data on measurements concerning follicular growth for those intending to manipulate
499 the *Asinina de Miranda's* cycles for assisted reproduction.

500

501 **6. Conflict of interest statement**

502 None of the authors has any financial or personal relationship that could
503 inappropriately influence or bias the content of the paper.

504

505 **7. Authors' participation**

506 MQ and RP-C conceived the study and participated in its design. MQ conducted the
507 animal reproductive assessment as well as the sequential blood collection and
508 ultrasound exams. MQ analysed and collected data from ultrasound films and
509 interpreted the data. In addition, MQ and RP-C were responsible for compiling the
510 literature review, drafting and finalizing the paper. Both authors read and approved
511 the final manuscript. Finally, both authors studied and addressed the issues raised in
512 the Review panel's comments, and together revised the manuscript.

513

514 **8. Acknowledgements**

515 We wish to thank AEPGA for providing the jennies and material used in the study
516 and M. Cristina Bastos de Carvalho for her help in feeding and handling the jennies
517 as well as in collecting data. We would also like to thank Dr. Celso Santos for his
518 help with progesterone measurements and Prof. Dr. Luis Ferreira for his help in
519 producing the Figure.

627 **Figure 1:** Serum progesterone and dominant follicle growth during the estrous cycle
628 for the *Asinina de Miranda* jennies (mean±standard error). The black bar corresponds
629 to the length of estrus. Values are presented in separate for single (A) and double
630 ovulations (B).

- 1 **Table 1:** Characteristics of the estrous cycle in *Asinina de Miranda* jennies in the
 2 breeding season.

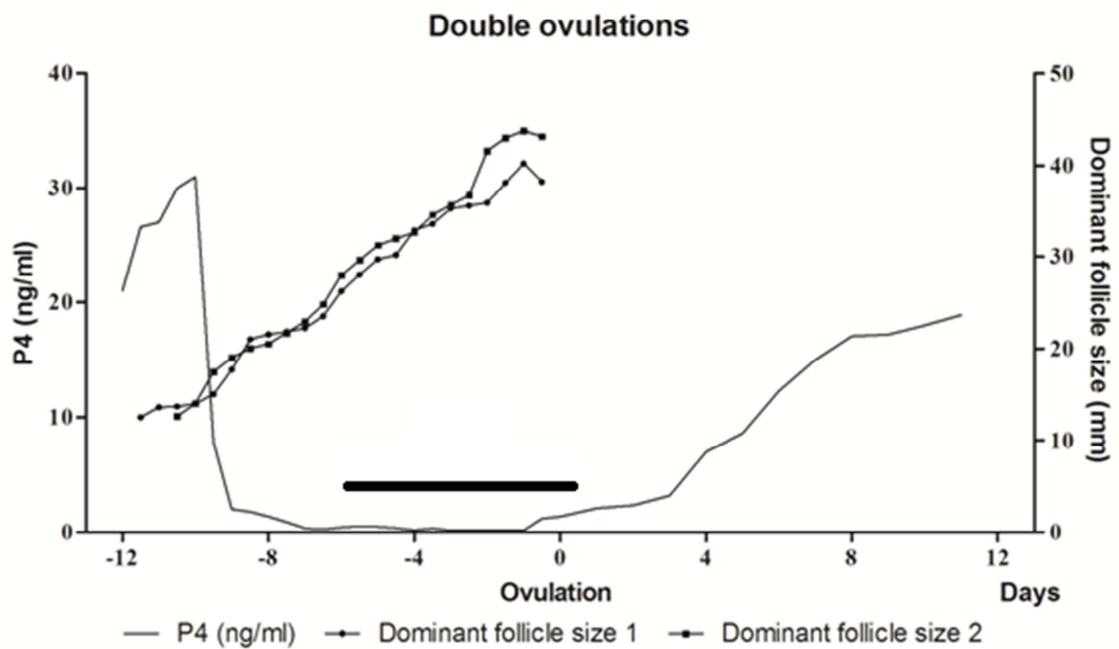

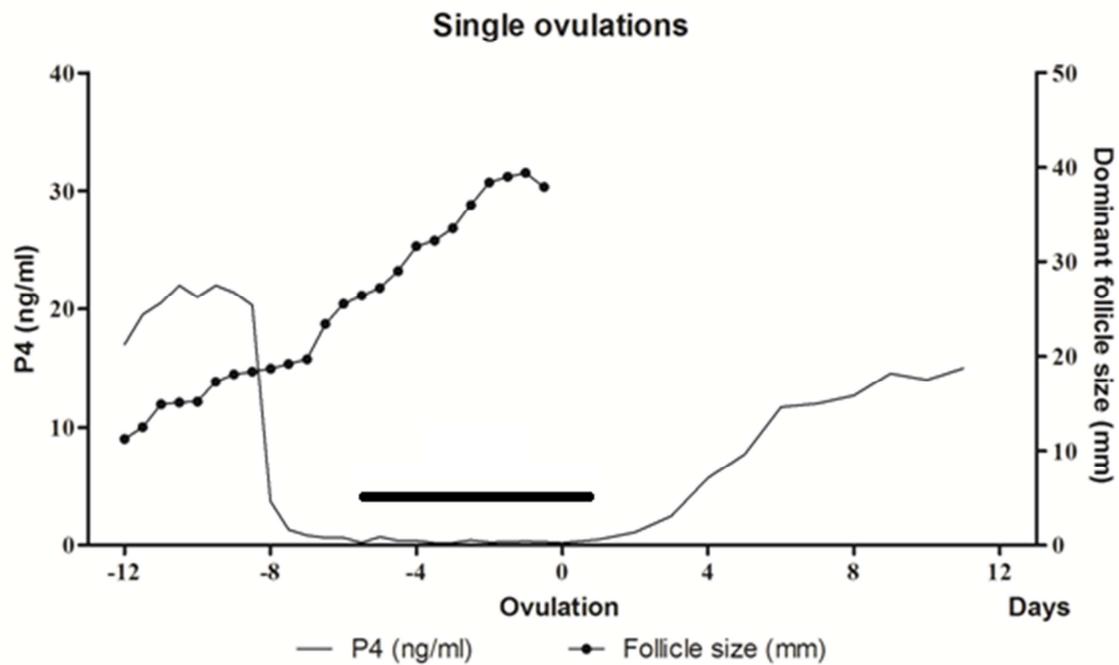

Type of ovulation	n	Parameter (days)	Mean \pm SE	Minimum - Maximum
Single	19	Length		
		Interovulatory interval	23.8 \pm 0.78	19.5 - 34.10
		Estrus	5.97 \pm 0.37*	3.15 \pm 8.89
		Diestrus	18.6 \pm 0.65	15.0 - 27.00
		Intervals		
		Onset of estrus to ovulation	5.22 \pm 0.40*	3.15 - 8.89
		Ovulation to end of estrus	0.74 \pm 0.17	0.00 - 1.87
Double	12	Length		
		Interovulatory interval	23.8 \pm 0.45	20.5 - 26.10
		Estrus	7.30 \pm 0.44*	4.34 - 9.71
		Diestrus	17.0 \pm 0.32	14.2 - 18.60
		Intervals		
		Onset of estrus to ovulation	6.80 \pm 0.27*	5.58 - 8.72
		Ovulation to end of estrus	0.496 \pm 0.35	(-)2.56 - 2.23
Triple	2	Length		
		Interovulatory interval	24.10 \pm 6.60	17.60 - 30.70
		Estrus	7.82 \pm 1.50	6.32 - 9.32
		Diestrus	16.20 \pm 4.62	11.60 - 20.90
		Intervals		
		Onset of estrus to ovulation	7.91 \pm 1.94	5.97 - 9.85
		Ovulation to end of estrus	(-)0.09 \pm 0.44	(-)0.53 - 0.35
Overall	33	Length		
		Interovulatory interval	23.80 \pm 0.55	17.60 - 34.70
		Estrus	6.56 \pm 0.30	3.15 - 9.71
		Diestrus	17.90 \pm 0.46	11.60 - 27.00
		Intervals		
		Onset of estrus to ovulation	5.96 \pm 0.31	1.70 - 9.85
		Ovulation to end of estrus	0.60 \pm 0.16	(-)2.56 - 2.23

- 3 *Differences were considered significant at a P < 0.05 level.

1 **Table 2:** Follicular development pattern in the breeding season for the *Asinina de*
 2 *Miranda* jennies.

Number of ovulations	<i>n</i>	Parameter (mm)	Mean \pm SE	Minimum - Maximum
Single	19	Dominant follicle size		
		At deviation	19.18 \pm 0.97	13,20 – 30.32
		At onset of estrus	29.20 \pm 1.41*	19.30 – 46.90
		MFD at ovulation	40.20 \pm 1.05*	31.80 – 47.90
		Daily growth rate		
		From deviation to onset of estrus	2.62 \pm 0.15	1.60 – 4.07
		From onset of estrus to ovulation	3.34 \pm 0.31	1.66 – 5.80
Double	24	Dominant follicle size		
		At deviation	17.00 \pm 0.95	15.90 – 25.25
		At onset of estrus	22.20 \pm 0.81*	15.74 – 31.79
		MFD at ovulation	36.70 \pm 0.86*	30.29 – 44.19
		Daily growth rate		
		From deviation to onset of estrus	2.63 \pm 1.86	0.05 – 8.33
		From onset of estrus to ovulation	3.10 \pm 0.25	1.49 - 6.02
Triple	6	Dominant follicle size		
		At deviation	21.57 \pm 4.62	14.09 – 43.56
		At onset of estrus	23.30 \pm 4.24	15.60 – 43.50
		MFD at ovulation	38.60 \pm 2.39	30.36 – 46.03
		Daily growth rate		
		From deviation to onset of estrus	2.41 \pm 0.48	0.05 – 3.13
		From onset of estrus to ovulation	3.05 \pm 0.64	1.57 – 5.14
Overall	49	Dominant follicle size		
		At deviation	18.46 \pm 0.83	15.29 – 43,50
		At onset of estrus	25.00 \pm 0.95	15.60 – 46.90
		MFD at ovulation	38.40 \pm 0.68	30.29 – 47.86
		Daily growth rate		
		From deviation to onset of estrus	2.60 \pm 0.19	0.05 – 5.83
		From onset of estrus to ovulation	3.18 \pm 0.18	1.49 – 5.80

3 *Differences were considered significant at a $P < 0.05$ level; MFD = maximum follicular diameter.

Highlights

- We revised the manuscript as requested.
- We reformulated the sentences that were less clear, and an English revision of the final manuscript form was undertaken
- Some concerns regarding the material and methods section were clarified

- This paper presents the lengths of the interestrus interval, estrus and diestrus in the Portuguese donkey breed *Asinina de Miranda*
- We also describe the ovulation rate in the studied population.
- Follicular growth rates and the sizes of the dominant follicle at the onset of estrus and at ovulation are detailed in single and multiple ovulations
- The total progesterone level in diestrus is compared in multiple and single ovulatory cycles.
